Spark Programming

we'll run Spark's interactive shell...

./bin/spark-shell

then from the "scala" REPL prompt, let's create some data...

val data = 1 to 10000

Spark Essentials: Master

The master parameter for a SparkContext determines which cluster to use

master	description	
local	run Spark locally with one worker thread (no parallelism)	
local[K]	run Spark locally with K worker threads (ideally set to # cores)	
spark://HOST:PORT	connect to a Spark standalone cluster; PORT depends on config (7077 by default)	
mesos://HOST:PORT connect to a Mesos cluster; PORT depends on config (5050 by default)		

create an RDD based on that data...

```
val distData = sc.parallelize(data)
```

then use a filter to select values less than 10...

```
distData.filter(_ < 10).collect()</pre>
```

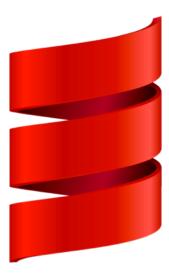

03: Getting Started

Spark Deconstructed

lecture: 20 min

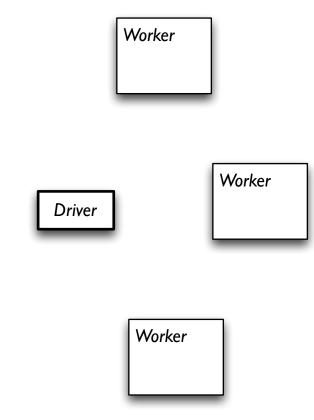

Let's spend a few minutes on this Scala thing...

scala-lang.org/

```
// load error messages from a log into memory
// then interactively search for various patterns
// https://gist.github.com/ceteri/8ae5b9509a08c08a1132
// base RDD
val lines = sc.textFile("hdfs://...")
// transformed RDDs
val errors = lines.filter(_.startsWith("ERROR"))
val messages = errors.map( .split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter( .contains("mysql")).count()
// action 2
messages.filter(_.contains("php")).count()
```

We start with Spark running on a cluster... submitting code to be evaluated on it:

```
val lines = sc.textFile("hdfs://...")

// transformed RDDs
val errors = lines.filter(_.startsWith("ERROR"))
val messages = errors.map(_.split("\t")).map(r => r(1))
messages.cache()

// action 1
messages.filter(_.contains("mysql")).count()

// discussing the other part
messages.filter(_.contains("php")).count()
```

At this point, take a look at the transformed RDD operator graph:

```
scala> messages.toDebugString
res5: String =
MappedRDD[4] at map at <console>:16 (3 partitions)
    MappedRDD[3] at map at <console>:16 (3 partitions)
    FilteredRDD[2] at filter at <console>:14 (3 partitions)
        MappedRDD[1] at textFile at <console>:12 (3 partitions)
        HadoopRDD[0] at textFile at <console>:12 (3 partitions)
```

```
// base RDD
val lines = sc.textFile("hdfs://...")
// transformed RDDs
val errors = lines.filter(_.startsWith("ERROR"))
val messages = errors.map(\_.split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter(_.contains("mysql")).count()
                                                        Worker
mediscussing the other part
                                                                 Worker
                                                 Driver
```

Worker

```
// base RDD
val lines = sc.textFile("hdfs://...")
// transformed RDDs
val errors = lines.filter(_.startsWith("ERROR"))
val messages = errors.map(\_.split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter(_.contains("mysql")).count()
                                                         Worker
                                                          block 1
mediscussing the other part
                                                                  Worker
                                                  Driver
                                                                   block 2
```

Worker

block 3

```
// base RDD
val lines = sc.textFile("hdfs://...")
// transformed RDDs
val errors = lines.filter( .startsWith("ERROR"))
val messages = errors.map(\_.split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter(_.contains("mysql")).count()
                                                         Worker
                                                          block 1
mediscussing the other part
                                                                  Worker
                                                  Driver
                                                                    block 2
                                                          Worker
                                                            block 3
```

```
// base RDD
val lines = sc.textFile("hdfs://...")
// transformed RDDs
val errors = lines.filter( .startsWith("ERROR"))
val messages = errors.map(\_.split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter(_.contains("mysql")).count()
                                                           Worker
                                                                       read
                                                                      HDFS
                                                            block
                                                                       block
mediscussing the other part
                                                                     Worker
                                                                                read
                                                                                HDFS
                                                    Driver
                                                                                block
                                                                      block 2
                                                            Worker
                                                                        read
                                                                        HDFS
                                                                        block
                                                             block 3
```

```
// base RDD

                                                        Driver
                                                                           block 2
                                                                      cache 3
                                                                                  process
                                                                                 from cache
                                                                 Worker
                                                                  block 3
```

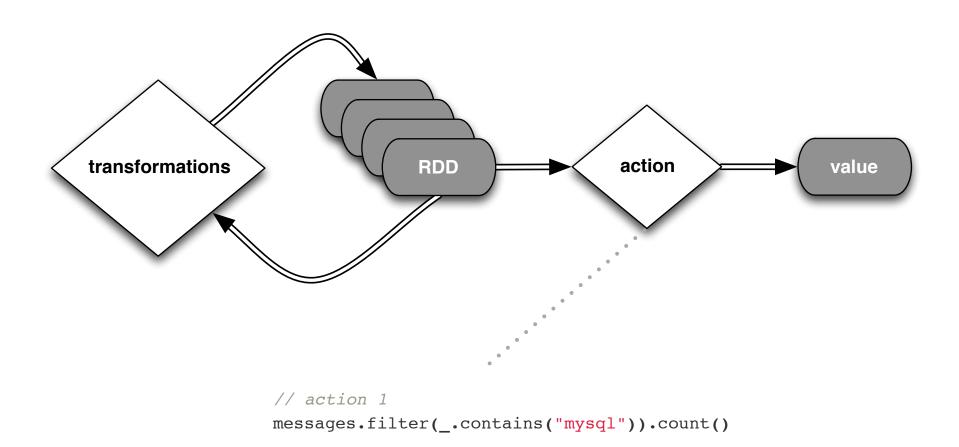

```
van eiscussien grenet of energy art
val messages = errors.map(_.split("\t")).map(r => r(1)
                                                                cache 1
                                                           Worker
// action 2
                                                            block 1
messages.filter(_.contains("php")).count()
                                                                         cache 2
                                                                     Worker
                                                    Driver
                                                                      block 2
                                                                 cache 3
                                                            Worker
                                                             block 3
```

Looking at the RDD transformations and actions from another perspective...

```
// load error messages from a log into memory
// then interactively search for various patterns
// https://gist.github.com/ceteri/8ae5b9509a08c08a1132
// base RDD
val lines = sc.textFile("hdfs://...")
                                                    transformations
                                                                                         action
// transformed RDDs
val errors = lines.filter(_.startsWith("ERROR"))
val messages = errors.map( .split("\t")).map(r => r(1))
messages.cache()
// action 1
messages.filter(_.contains("mysql")).count()
// action 2
messages.filter(_.contains("php")).count()
```

04: Getting Started

Simple Spark Apps

lab: 20 min

Simple Spark Apps: WordCount

Definition:

count how often each word appears in a collection of text documents

This simple program provides a good test case for parallel processing, since it:

- requires a minimal amount of code
- demonstrates use of both symbolic and numeric values
- isn't many steps away from search indexing
- serves as a "Hello World" for Big Data apps

A distributed computing framework that can run WordCount **efficiently in parallel at scale** can likely handle much larger and more interesting compute problems

```
void map (String doc_id, String text):
  for each word w in segment(text):
    emit(w, "1");

void reduce (String word, Iterator group):
  int count = 0;

for each pc in group:
    count += Int(pc);

emit(word, String(count));
```

Simple Spark Apps: WordCount

Scala:

```
val f = sc.textFile("README.md")
val wc = f.flatMap(l => l.split(" ")).map(word => (word, 1)).reduceByKey(_ + _)
wc.saveAsTextFile("wc_out.txt")
```

Python:

```
from operator import add
f = sc.textFile("README.md")
wc = f.flatMap(lambda x: x.split(' ')).map(lambda x: (x, 1)).reduceByKey(add)
wc.saveAsTextFile("wc_out.txt")
```

Simple Spark Apps: Assignment

Using the README.md and CHANGES.txt files in the Spark directory:

- create RDDs to filter each line for the keyword "Spark"
- 2. perform a WordCount on each, i.e., so the results are (K,V) pairs of (word, count)
- 3. join the two RDDs

Table 4-2. Transformations on two pair RDDs $(rdd = \{(1, 2), (3, 4), (3, 6)\}\)$ other $= \{(3, 9)\}\)$

Function name	Purpose	Example	Result
subtractByKey	Remove elements with a key present in the other RDD.	rdd.subtractByKey(other)	{(1, 2)}
join	Perform an inner join between two RDDs.	rdd.join(other)	{(3, (4, 9)), (3, (6, 9))}
rightOuterJoin	Perform a join between two RDDs where the key must be present in the first RDD.	rdd.rightOuterJoin(other)	{(3,(Some(4),9)), (3,(Some(6),9))}
leftOuterJoin	Perform a join between two RDDs where the key must be present in the other RDD.	rdd.leftOuterJoin(other)	{(1,(2,None)), (3, (4,Some(9))), (3, (6,Some(9)))}
cogroup	Group data from both RDDs sharing the same key.	rdd.cogroup(other)	{(1,([2],[])), (3, ([4, 6],[9]))}

Example 4-17. Scala shell inner join

```
storeAddress = {
    (Store("Ritual"), "1026 Valencia St"), (Store("Philz"), "748 Van Ness Ave"),
    (Store("Philz"), "3101 24th St"), (Store("Starbucks"), "Seattle")}

storeRating = {
    (Store("Ritual"), 4.9), (Store("Philz"), 4.8))}

storeAddress.join(storeRating) == {
    (Store("Ritual"), ("1026 Valencia St", 4.9)),
    (Store("Philz"), ("748 Van Ness Ave", 4.8)),
    (Store("Philz"), ("3101 24th St", 4.8))}
```

```
Spark join example, leftOuterJoin example, rightOuterJoin example

1    scala> val names1 = sc.parallelize(List("abe", "abby", "apple")).map(a => (a, 1))
2    names1: org.apache.spark.rdd.RDD[(String, Int)] = MappedRDD[1441] at map at <console>:14

3    scala> val names2 = sc.parallelize(List("apple", "beatty", "beatrice")).map(a => (a, 1))
5    names2: org.apache.spark.rdd.RDD[(String, Int)] = MappedRDD[1443] at map at <console>:14

6    scala> names1.join(names2).collect
7    res735: Array[(String, (Int, Int))] = Array((apple,(1,1)))

9    scala> names1.leftOuterJoin(names2).collect
11    res736: Array[(String, (Int, Option[Int]))] = Array((abby,(1,None)), (apple,(1,Some(1))), (abe, (1,None)))

12    scala> names1.rightOuterJoin(names2).collect
13    res737: Array[(String, (Option[Int], Int))] = Array((apple,(Some(1),1)), (beatty,(None,1)), (beatrice,(None,1)))
```

Simple Spark Apps: Assignment

Using the the Spark directory:

1. create RDDs to filter each file for the keyword

- Checkpoint:
 how many "Spark" keywords?
- 3. join the two RDDs

03: Intro Spark Apps

Spark Essentials

lecture/lab: 45 min

Spark Essentials:

Intro apps, showing examples in both Scala and Python...

Let's start with the basic concepts in:

spark.apache.org/docs/latest/scalaprogramming-guide.html

using, respectively:

- ./bin/spark-shell
- ./bin/pyspark

alternatively, with IPython Notebook:

IPYTHON_OPTS="notebook --pylab inline" ./bin/pyspark

Spark Essentials: SparkContext

First thing that a Spark program does is create a SparkContext object, which tells Spark how to access a cluster

In the shell for either Scala or Python, this is the sc variable, which is created automatically

Other programs must use a constructor to instantiate a new SparkContext

Then in turn SparkContext gets used to create other variables

Spark Essentials: SparkContext

Scala:

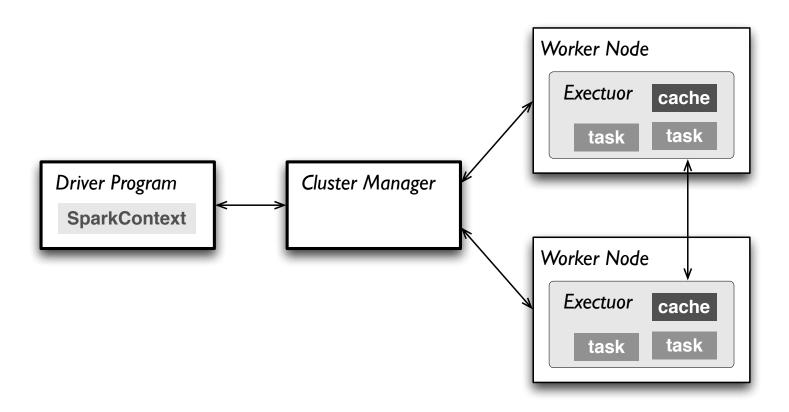

```
scala> sc
res: spark.SparkContext = spark.SparkContext@470d1f30
```

Python:

```
>>> sc
<pyspark.context.SparkContext object at 0x7f7570783350>
```

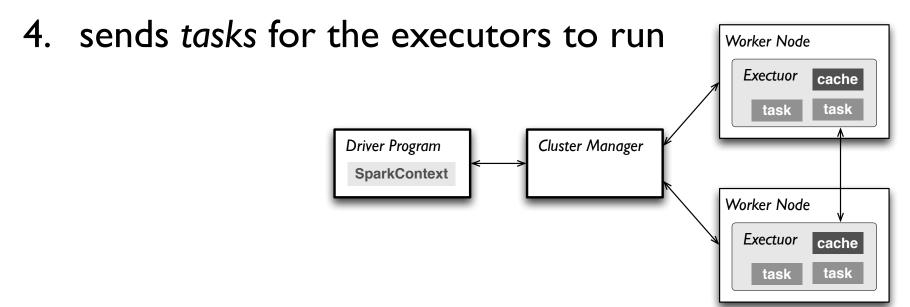

Spark Essentials: Master

spark.apache.org/docs/latest/clusteroverview.html

Spark Essentials: Master

- I. connects to a *cluster manager* which allocate resources across applications
- 2. acquires executors on cluster nodes worker processes to run computations and store data
- 3. sends app code to the executors

Resilient Distributed Datasets (RDD) are the primary abstraction in Spark – a fault-tolerant collection of elements that can be operated on in parallel

There are currently two types:

- parallelized collections take an existing Scala collection and run functions on it in parallel
- Hadoop datasets run functions on each record of a file in Hadoop distributed file system or any other storage system supported by Hadoop

- two types of operations on RDDs: transformations and actions
- transformations are lazy (not computed immediately)
- the transformed RDD gets recomputed when an action is run on it (default)
- however, an RDD can be persisted into storage in memory or disk

Scala:

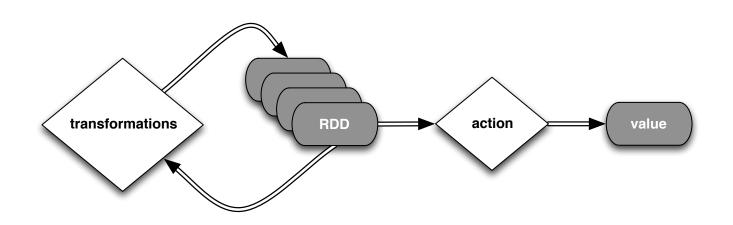

```
scala> val data = Array(1, 2, 3, 4, 5)
data: Array[Int] = Array(1, 2, 3, 4, 5)

scala> val distData = sc.parallelize(data)
distData: spark.RDD[Int] = spark.ParallelCollection@10d13e3e
```

```
>>> data = [1, 2, 3, 4, 5]
>>> data
[1, 2, 3, 4, 5]
>>> distData = sc.parallelize(data)
>>> distData
ParallelCollectionRDD[0] at parallelize at PythonRDD.scala:229
```

Spark can create RDDs from any file stored in HDFS or other storage systems supported by Hadoop, e.g., local file system, Amazon S3, Hypertable, HBase, etc.

Spark supports text files, SequenceFiles, and any other Hadoop InputFormat, and can also take a directory or a glob (e.g. /data/201404*)

Scala:

```
scala> val distFile = sc.textFile("README.md")
distFile: spark.RDD[String] = spark.HadoopRDD@1d4cee08
```

```
>>> distFile = sc.textFile("README.md")
14/04/19 23:42:40 INFO storage.MemoryStore: ensureFreeSpace(36827) called
with curMem=0, maxMem=318111744
14/04/19 23:42:40 INFO storage.MemoryStore: Block broadcast_0 stored as
values to memory (estimated size 36.0 KB, free 303.3 MB)
>>> distFile
MappedRDD[2] at textFile at NativeMethodAccessorImpl.java:-2
```

Transformations create a new dataset from an existing one

All transformations in Spark are *lazy*: they do not compute their results right away – instead they remember the transformations applied to some base dataset

- optimize the required calculations
- recover from lost data partitions

transformation	description
map(func)	return a new distributed dataset formed by passing each element of the source through a function func
filter(func)	return a new dataset formed by selecting those elements of the source on which <i>func</i> returns true
flatMap(func)	similar to map, but each input item can be mapped to 0 or more output items (so <i>func</i> should return a Seq rather than a single item)
<pre>sample(withReplacement, fraction, seed)</pre>	sample a fraction fraction of the data, with or without replacement, using a given random number generator seed
union(otherDataset)	return a new dataset that contains the union of the elements in the source dataset and the argument
<pre>distinct([numTasks]))</pre>	return a new dataset that contains the distinct elements of the source dataset

transformation	description
<pre>groupByKey([numTasks])</pre>	when called on a dataset of (K, V) pairs, returns a dataset of (K, Seq[V]) pairs
reduceByKey(func, [numTasks])	when called on a dataset of (K, V) pairs, returns a dataset of (K, V) pairs where the values for each key are aggregated using the given reduce function
<pre>sortByKey([ascending], [numTasks])</pre>	when called on a dataset of (K, V) pairs where K implements Ordered, returns a dataset of (K, V) pairs sorted by keys in ascending or descending order, as specified in the boolean ascending argument
<pre>join(otherDataset, [numTasks])</pre>	when called on datasets of type (K, V) and (K, W) , returns a dataset of $(K, (V, W))$ pairs with all pairs of elements for each key
<pre>cogroup(otherDataset, [numTasks])</pre>	when called on datasets of type (K, V) and (K, W), returns a dataset of (K, Seq[V], Seq[W]) tuples — also called groupWith
cartesian(otherDataset)	when called on datasets of types T and U, returns a dataset of (T, U) pairs (all pairs of elements)

Scala:

```
val distFile = sc.textFile("README.md") 
distFile.map(l => l.split(" ")).collect()

distFile.flatMap(l => l.split(" ")).collect()
```

```
distFile = sc.textFile("README.md")
distFile.map(lambda x: x.split(' ')).collect()
distFile.flatMap(lambda x: x.split(' ')).collect()
```

Scala:

```
val distFile = sc.textFile("README.md")
distFile.map(l => l.split(" ")).collect()
distFile.flatMap(l => l.split(" ")).collect()

Python:
distFile = sc.textFile("README.md")
distFile.map(lambda x: x.split(' ')).collect()
distFile.flatMap(lambda x: x.split(' ')).collect()
```

Scala:

```
val distFile = sc.textFile("README.md")
distFile.map(l => l.split(" ")).collect()
distFile.flatMap(l => l.split(" ")).collect()

Python:
distFile = sc.textFile("README.md")
distFile.map(lambda x: x.split(' ')).collect()
distFile.flatMap(lambda x: x.split(' ')).collect()
```

looking at the output, how would you compare results for map() vs. flatMap()?

Spark Essentials: Actions

action	description
reduce(func)	aggregate the elements of the dataset using a function func (which takes two arguments and returns one), and should also be commutative and associative so that it can be computed correctly in parallel
collect()	return all the elements of the dataset as an array at the driver program – usually useful after a filter or other operation that returns a sufficiently small subset of the data
count()	return the number of elements in the dataset
first()	return the first element of the dataset – similar to $take(I)$
take(n)	return an array with the first n elements of the dataset – currently not executed in parallel, instead the driver program computes all the elements
<pre>takeSample(withReplacement, fraction, seed)</pre>	return an array with a random sample of <i>num</i> elements of the dataset, with or without replacement, using the given random number generator seed

Spark Essentials: Actions

action	description
<pre>saveAsTextFile(path)</pre>	write the elements of the dataset as a text file (or set of text files) in a given directory in the local filesystem, HDFS or any other Hadoop-supported file system. Spark will call toString on each element to convert it to a line of text in the file
saveAsSequenceFile(path)	write the elements of the dataset as a Hadoop SequenceFile in a given path in the local filesystem, HDFS or any other Hadoop-supported file system. Only available on RDDs of key-value pairs that either implement Hadoop's Writable interface or are implicitly convertible to Writable (Spark includes conversions for basic types like Int, Double, String, etc).
countByKey()	only available on RDDs of type (K, V). Returns a 'Map' of (K, Int) pairs with the count of each key
foreach(func)	run a function func on each element of the dataset – usually done for side effects such as updating an accumulator variable or interacting with external storage systems

Spark Essentials: Actions

Scala:

```
val f = sc.textFile("README.md")
val words = f.flatMap(l => l.split(" ")).map(word => (word, 1))
words.reduceByKey(_ + _).collect.foreach(println)
```

```
from operator import add
f = sc.textFile("README.md")
words = f.flatMap(lambda x: x.split(' ')).map(lambda x: (x, 1))
words.reduceByKey(add).collect()
```

Spark Essentials: Persistence

Spark can *persist* (or cache) a dataset in memory across operations

Each node stores in memory any slices of it that it computes and reuses them in other actions on that dataset – often making future actions more than 10x faster

The cache is fault-tolerant: if any partition of an RDD is lost, it will automatically be recomputed using the transformations that originally created it

Spark Essentials: Persistence

transformation	description
MEMORY_ONLY	Store RDD as deserialized Java objects in the JVM. If the RDD does not fit in memory, some partitions will not be cached and will be recomputed on the fly each time they're needed. This is the default level.
MEMORY_AND_DISK	Store RDD as deserialized Java objects in the JVM. If the RDD does not fit in memory, store the partitions that don't fit on disk, and read them from there when they're needed.
MEMORY_ONLY_SER	Store RDD as serialized Java objects (one byte array per partition). This is generally more space-efficient than deserialized objects, especially when using a fast serializer, but more CPU-intensive to read.
MEMORY_AND_DISK_SER	Similar to MEMORY_ONLY_SER, but spill partitions that don't fit in memory to disk instead of recomputing them on the fly each time they're needed.
DISK_ONLY	Store the RDD partitions only on disk.
MEMORY_ONLY_2, MEMORY_AND_DISK_2, etc	Same as the levels above, but replicate each partition on two cluster nodes.

Spark Essentials: Persistence

Scala:

```
val f = sc.textFile("README.md")
val w = f.flatMap(l => l.split(" ")).map(word => (word, 1)).cache()
w.reduceByKey(_ + _).collect.foreach(println)
```

```
from operator import add
f = sc.textFile("README.md")
w = f.flatMap(lambda x: x.split(' ')).map(lambda x: (x, 1)).cache()
w.reduceByKey(add).collect()
```

Spark Essentials: Broadcast Variables

Broadcast variables let programmer keep a read-only variable cached on each machine rather than shipping a copy of it with tasks

For example, to give every node a copy of a large input dataset efficiently

Spark also attempts to distribute broadcast variables using efficient broadcast algorithms to reduce communication cost

Spark Essentials: Broadcast Variables

Scala:

```
val broadcastVar = sc.broadcast(Array(1, 2, 3))
broadcastVar.value
```

```
broadcastVar = sc.broadcast(list(range(1, 4)))
broadcastVar.value
```

Spark Essentials: Accumulators

Accumulators are variables that can only be "added" to through an associative operation

Used to implement counters and sums, efficiently in parallel

Spark natively supports accumulators of numeric value types and standard mutable collections, and programmers can extend for new types

Only the driver program can read an accumulator's value, not the tasks

Spark Essentials: Accumulators

Scala:

```
val accum = sc.accumulator(0)
sc.parallelize(Array(1, 2, 3, 4)).foreach(x => accum += x)
accum.value
```

```
accum = sc.accumulator(0)
rdd = sc.parallelize([1, 2, 3, 4])
def f(x):
    global accum
    accum += x

rdd.foreach(f)
accum.value
```

Spark Essentials: Accumulators

Scala:

```
val accum = sc.accumulator(0)
sc.parallelize(Array(1, 2, 3, 4)).foreach(x => accum += x)
accum.value
                                                    driver-side
Python:
accum = sc.accumulator(0)
rdd = sc.parallelize([1, 2, 3, 4])
def f(x):
   global accum
   accum += x
rdd.foreach(f)
accum.value
```

Spark Essentials: (K,V) pairs

Scala:

```
val pair = (a, b)

pair._1 // => a
pair._2 // => b
```

Python:

```
pair = (a, b)

pair[0] # => a
pair[1] # => b
```

Java:

```
Tuple2 pair = new Tuple2(a, b);

pair._1 // => a
pair._2 // => b
```

Spark Essentials: API Details

For more details about the Scala/Java API:

spark.apache.org/docs/latest/api/scala/index.html#org.apache.spark.package

For more details about the Python API:

spark.apache.org/docs/latest/api/python/

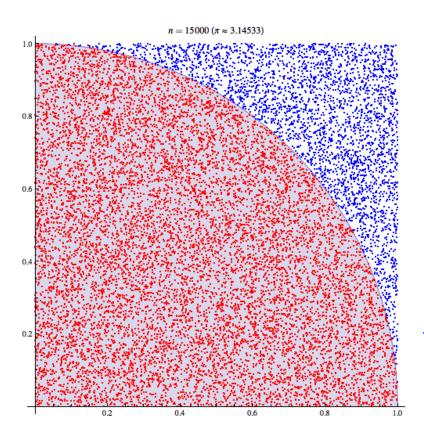

03: Intro Spark Apps

Spark Examples

lecture/lab: 10 min

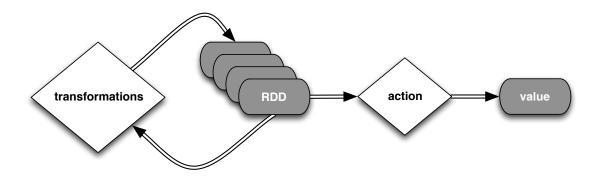

Next, try using a Monte Carlo method to estimate the value of Pi

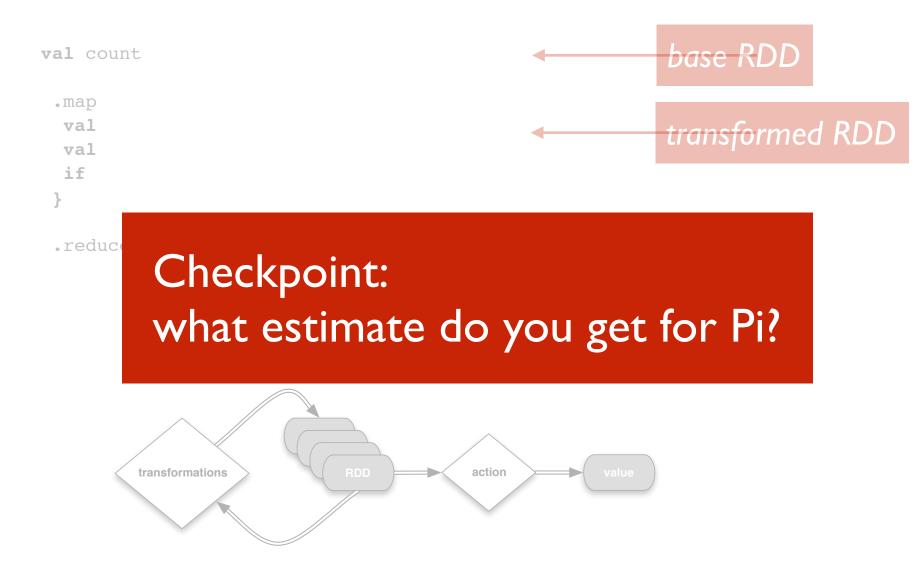

./bin/run-example SparkPi 2 local

wikipedia.org/wiki/Monte_Carlo_method

```
import scala.math.random
import org.apache.spark.
/** Computes an approximation to pi */
object SparkPi {
 def main(args: Array[String]) {
   val conf = new SparkConf().setAppName("Spark Pi")
   val spark = new SparkContext(conf)
   val slices = if (args.length > 0) args(0).toInt else 2
   val n = 100000 * slices
   val count = spark.parallelize(1 to n, slices).map { i =>
      val x = random * 2 - 1
     val v = random * 2 - 1
      if (x*x + y*y < 1) 1 else 0
    }.reduce( + )
    println("Pi is roughly " + 4.0 * count / n)
    spark.stop()
```

Spark Examples: K-Means

Next, try using K-Means to cluster a set of vector values:

```
cp ../data/examples-data/kmeans_data.txt .
./bin/run-example SparkKMeans kmeans_data.txt 3 0.01 local
```

Based on the data set:

If you can't run this example, substitute LocalKMeans for SparkKMeans

```
0.0 0.0 0.0
```

0.1 0.1 0.1

0.2 0.2 0.2

9.0 9.0 9.0

9.1 9.1 9.1

9.2 9.2 9.2

Please refer to the source code in:

examples/src/main/scala/org/apache/spark/examples/SparkKMeans.scala

Spark Examples: PageRank

Next, try using PageRank to rank the relationships in a graph:

```
cp ../data/examples-data/pagerank_data.txt .
./bin/run-example SparkPageRank pagerank_data.txt 10 local
```

Based on the data set:

Before running this example, you would need to put the pagerank_data.txt file on HDFS. Remember, all mllib files are at: \$SPARK_HOME/data/mllib

- 1 2
- 1 3
- 1 4
- 2 1
- 3 1
- 4 1

Please refer to the source code in:

examples/src/main/scala/org/apache/spark/examples/SparkPageRank.scala

Data Workflows: MLlib

spark.apache.org/docs/latest/mllib-guide.html

```
val data = // RDD of Vector
val model = KMeans.train(data, k=10)
```

MLI:An API for Distributed Machine Learning
